

Computer vision course

Lab 2 - Filters and histogram equalization

Task 1

Write a program that loads the image provided (image.jpg) and shows it. It then converts the image to grayscale (cv::cvtColor() function) and saves it with the image_grayscale.jpg name.

Consider this last image for the next tasks.

Task 2 min and max are in separate files

Expand Task 1 implementing a max filter and a min filter in two dedicated functions (implemented by you in a separate source file) that manipulate the pixels directly. Such functions accept an integer representing the size of the kernel, and check that it is an odd number. If it is even, the function does not process the image. Apply the filters using several kernel sizes and find the best option that removes the electric cables in the background without corrupting the image too much.

Task 3

Expand Task 2 using the median filter and the gaussian smoothing filter provided by OpenCV. Show the results.

Task 4

Expand Task 1 plotting the histogram of the image using 256 bins and range [0, 255]. Try also other values for the number of bins.

Task 5

Expand Task 4 including histogram equalization using the dedicated OpenCV function and visualize the result.
